Martingales and Measures

Chapter 21

Options, Futures, and Other Derivatives, 5th edition © 2002 by John C. Hull

21.2

Derivatives Dependent on a Single Underlying Variable

Consider a variable, θ , (not necessarily the price of a traded security) that follows the process

$$\frac{d\theta}{\theta} = m dt + s dz$$

Imagine two derivatives dependent on θ with prices f_1 and f_2 . Suppose

$$\frac{df_1}{f_1} = \mu_1 dt + \sigma_1 dz$$

$$\frac{df_2}{f_2} = \mu_2 dt + \sigma_2 dz$$

Options, Futures, and Other Derivatives, 5th edition © 2002 by John C. Hull

21.3

Forming a Riskless Portfolio

We can set up a riskless portfolio Π , consisting of

+ $\sigma_2 f_2$ of the 1st derivative and

– $\sigma_1 f_1$ of the 2nd derivative

$$\Pi = (\sigma_2 f_2) f_1 - (\sigma_1 f_1) f_2$$

$$\delta \Pi = (\mu_1 \sigma_2 f_1 f_2 - \mu_2 \sigma_1 f_1 f_2) \delta t$$

Options, Futures, and Other Derivatives, 5th edition © 2002 by John C. Hull

21.4

Market Price of Risk (Page 485)

Since the portfolio is riskless: $\delta \Pi = r \Pi \delta t$

This gives: $\mu_1 \sigma_2 - \mu_2 \sigma_1 = r \sigma_2 - r \sigma_1$

or
$$\frac{\mu_1 - r}{\sigma_1} = \frac{\mu_2 - r}{\sigma_2}$$

- This shows that $(\mu - r)/\sigma$ is the same for all derivatives dependent on the same underlying variable, θ
- We refer to $(\mu - r)/\sigma$ as the market price of risk for θ and denote it by λ

Options, Futures, and Other Derivatives, 5th edition © 2002 by John C. Hull

21.5

Extension of the Analysis to Several Underlying Variables (Equations 21.12 and 21.13, page 487)

If f depends on several underlying variables with

$$\frac{df}{f} = \mu dt + \sum_{i=1}^n \sigma_i dz_i$$

then

$$\mu - r = \sum_{i=1}^n \lambda_i \sigma_i$$

21.6

Martingales (Page 488)

- A martingale is a stochastic process with zero drift
- A variable following a martingale has the property that its expected future value equals its value today

Options, Futures, and Other Derivatives, 5th edition © 2002 by John C. Hull

21.7

Alternative Worlds

In the traditional risk-neutral world

$$df = rf dt + \sigma f dz$$

In a world where the market price of risk is λ

$$df = (r + \lambda\sigma)f dt + \sigma f dz$$

Options, Futures, and Other Derivatives, 5th edition © 2002 by John C. Hull

21.8

A Key Result (Page 489)

If we set λ equal to the volatility of a security g , then Ito's lemma shows that f/g is a martingale for all derivative security prices f (f and g are assumed to provide no income during the period under consideration)

Options, Futures, and Other Derivatives, 5th edition © 2002 by John C. Hull

21.9

Forward Risk Neutrality

We refer to a world where the market price of risk is the volatility of g as a world that is forward risk neutral with respect to g .

If E_g denotes a world that is FRN wrt g

$$\frac{f_0}{g_0} = E_g \left(\frac{f_T}{g_T} \right)$$

21.10

Alternative Choices for the Numeraire Security g

- Money Market Account
- Zero-coupon bond price
- Annuity factor

Options, Futures, and Other Derivatives, 5th edition © 2002 by John C. Hull

21.11

Money Market Account as the Numeraire

- The money market account is an account that starts at \$1 and is always invested at the short-term risk-free interest rate
- The process for the value of the account is

$$dg = r g dt$$
- This has zero volatility. Using the money market account as the numeraire leads to the traditional risk-neutral world

Options, Futures, and Other Derivatives, 5th edition © 2002 by John C. Hull

21.12

Money Market Account continued

Since $g_0 = 1$ and $g_T = e^{\int_0^T r dt}$, the equation

$$\frac{f_0}{g_0} = E_g \left(\frac{f_T}{g_T} \right)$$

becomes

$$f_0 = \hat{E} \left[e^{-\int_0^T r dt} f_T \right]$$

where \hat{E} denotes expectations in the traditional risk-neutral world

Options, Futures, and Other Derivatives, 5th edition © 2002 by John C. Hull

21.13

Zero-Coupon Bond Maturing at time T as Numeraire

The equation

$$\frac{f_0}{g_0} = E_g \left(\frac{f_T}{g_T} \right)$$

becomes

$$f_0 = P(0, T) E_T[f_T]$$

where $P(0, T)$ is the zero-coupon bond price and E_T denotes expectations in a world that is FRN wrt the bond price

Options, Futures, and Other Derivatives, 5th edition © 2002 by John C. Hull

21.14

Forward Prices

In a world that is FRN wrt $P(0, T)$, the expected value of a security at time T is its forward price

Options, Futures, and Other Derivatives, 5th edition © 2002 by John C. Hull

21.15

Interest Rates

In a world that is FRN wrt $P(0, T_2)$ the expected value of an interest rate lasting between times T_1 and T_2 is the forward interest rate

Options, Futures, and Other Derivatives, 5th edition © 2002 by John C. Hull

21.16

Annuity Factor as the Numeraire

The equation

$$\frac{f_0}{g_0} = E_g \left(\frac{f_T}{g_T} \right)$$

becomes

$$f_0 = A(0) E_A \left[\frac{f_T}{A(T)} \right]$$

Options, Futures, and Other Derivatives, 5th edition © 2002 by John C. Hull

21.17

Annuity Factors and Swap Rates

Suppose that $s(t)$ is the swap rate corresponding to the annuity factor A .

Then:

$$s(t) = E_A[s(T)]$$

Options, Futures, and Other Derivatives, 5th edition © 2002 by John C. Hull

21.18

Extension to Several Independent Factors (Page 492)

In the traditional risk-neutral world

$$df(t) = r(t)f(t)dt + \sum_{i=1}^m \sigma_{f,i}(t)f(t)dz_i$$

$$dg(t) = r(t)g(t)dt + \sum_{i=1}^m \sigma_{g,i}(t)g(t)dz_i$$

For other worlds that are internally consistent

$$df(t) = \left[r(t) + \sum_{i=1}^m \lambda_i \sigma_{f,i}(t) \right] f(t)dt + \sum_{i=1}^m \sigma_{f,i}(t)f(t)dz_i$$

$$dg(t) = \left[r(t) + \sum_{i=1}^m \lambda_i \sigma_{g,i}(t) \right] g(t)dt + \sum_{i=1}^m \sigma_{g,i}(t)g(t)dz_i$$

Quantos continued

When we move from the traditional risk neutral world in currency Y to the traditional risk neutral world in currency X , the growth rate of a variable V increases by

$$\rho\sigma_V\sigma_S$$

where σ_V is the volatility of V , σ_S is the volatility of the exchange rate (units of Y per unit of X), and ρ is the coefficient of correlation between the two

Options, Futures, and Other Derivatives, 5th edition © 2002 by John C. Hull

Siegel's Paradox

An exchange rate S (units of currency Y per unit of currency X) follows the risk - neutral process

$$dS = [r_Y - r_X]Sdt + \sigma_S Sdz$$

This implies from Ito's lemma that

$$d(1/S) = [r_X - r_Y + \sigma_S^2](1/S)dt - \sigma_S(1/S)dz$$

Given that the process for S has a drift rate of $r_Y - r_X$, we expect the process for $1/S$ to have a drift of $r_X - r_Y$.

What is going on here?
